
Command Reference: CreateDataStoreDataDictionary()

Create an HTML data dictionary for a datastore

Version 11.02.00, 2015-05-11

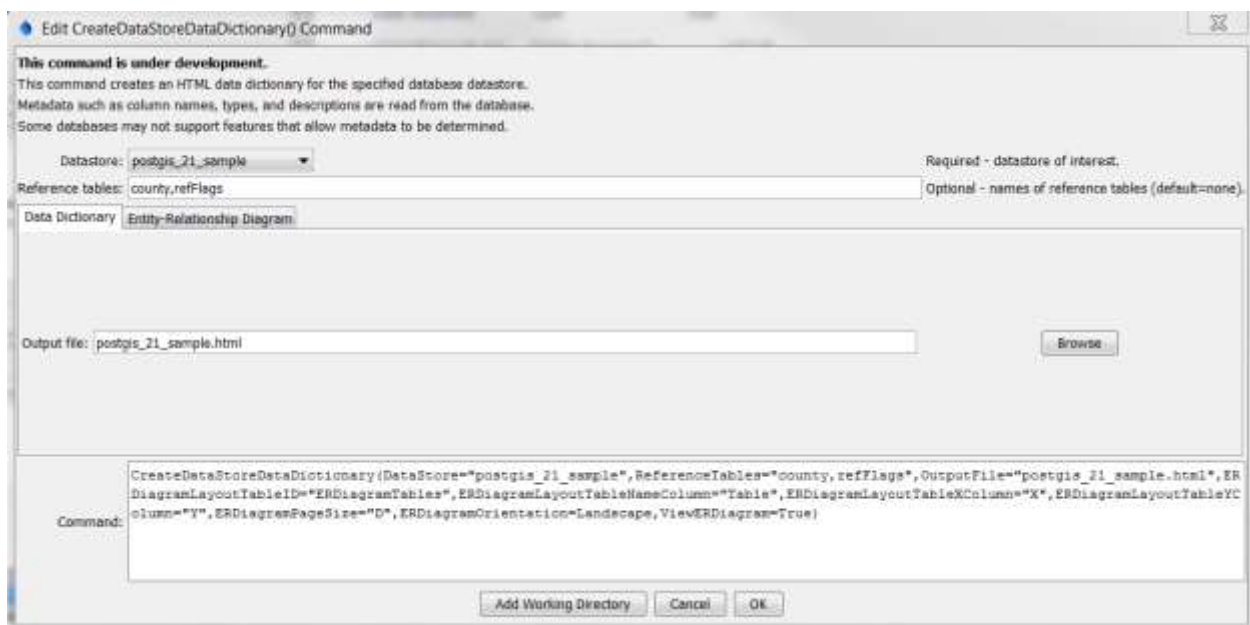

The `CreateDataStoreDataDictionary()` command creates an HTML data dictionary and Entity Relationship (ER) Diagram for a database datastore. This command is under development and will be enhanced as resources allow. The `Java DatabaseMetaData` class is used to access database metadata. Current limitations are as follows:

- The command has been tested with SQL Server, Microsoft Access, and PostgreSQL databases. The command may or may not work with other databases.
- SQL Server is supported to a limited degree. Table and column descriptions currently cannot be retrieved due to limitations in SQL Server database drivers.
- Data dictionary output is only as complete as the metadata defined by the database administrator – there currently is no way to provide additional information via the command.
- The ER Diagram capability is under development.

The data dictionary output from the command is an HTML file that provides:

- General database information.
- A list of tables and views, which link to table details.
- For each table, the details for the columns in the table, including name, data type, remarks (description), whether null is allowed, and indication of whether the columns are primary or foreign keys.
- Reference tables have all of their data listed to help understand relationships.

The following dialog is used to edit the command and illustrates the syntax for the command:

CreateDataStoreDataDictionary() Command Editor for Data Dictionary Parameters

CreateDataStoreDataDictionary() Command Editor for Entity Relationship Diagram Parameters

The command syntax is as follows:

```
CreateDataStoreDataDictionary (Parameter=Value, ...)
```

Command Parameters

Parameter	Description	Default
DataStore	The name of a database datastore.	None – must be specified.
ReferenceTables	A list of database reference tables. The content of these tables will be output in their entirety.	No reference tables
OutputFile	The name of the file for the HTML data dictionary. The name can contain \${Property} notation to insert processor property values in the filename.	None.
ERDiagram LayoutTableID	The table identifier for the table supplying ER Diagram coordinate information.	None – must be specified if ER Diagram is created.
ERDiagramLayout TableXColumn	The name of the column in the layout table containing the X coordinates for the ER Diagram. Coordinates should be specified in points (1/72 of inch) as position on page size.	None – must be specified.
ERDiagramLayout TableYColumn	The name of the column in the layout table containing the Y coordinates for the ER Diagram.	None – must be specified.
ERDiagram PageSize	The page size for the ER Diagram layout. Currently this defaults to 11x17 (B).	B
ERDiagram Orientation	The orientation of the ER Diagram.	Landscape
ViewERDiagram	Indicate whether the ER Diagram should be shown in a window when the commands are run.	False

The following is an example of an Excel workbook with ER Diagram layout data.

	A	B	C
1	Table	X	Y
2	addr	41.68	64.42
3	addrfeat	62.53	96.63
4	bg	83.37	128.84
5	countysub_lookup	104.21	161.05
6	county_lookup	125.05	193.26
7	cousub	145.89	225.47
8	direction_lookup	166.74	257.68
