Command Reference: RunPython()

Run a Python script

The RunPython () command runs a Python script, waiting until execution is finished before processing additional commands. Python is a powerful scripting language that is widely used (see http://www.python.org). This command allows Python scripts to be run using a variety of Python interpreters, as shown in the following table. It is assumed that Python is installed in the standard directory for the distribution. New versions of Python will reside in similar locations to those shown below

RunPython() Supported Python Interpreters

Interpreter	Language, Program Name		
(Website)	(Example Install Home)	Comments	
IronPython	.NET, ipy	Useful for integrating with .NET	
(ironpython.net)	$(C:\Program\ Files\Iron\Python\ 2.6)$	applications, in particular to manipulate	
		Microsoft Office software data files. Can	
		use .NET assembly code (but this code in	
		a Python script is only recognized by	
		IronPython). Integration can occur within	
		a running .NET application (essentially	
		extending the functionality of the .NET	
		application). Version 2.6 requires .NET	
		2.0. Version 2.6.1 requires .NET 4.0.	
Jython	Java, jython	Useful for integrating with Java	
(www.jython.org)	$(C:\)$ <i>jython2.5.1</i>)	applications, such as TSTool. Can use Java code (but this code in a Python script	
		is only recognized by Jython).	
Jython embedded	Java	Useful for integrating with Java	
(www.jython.org)	($C:\$) $jython 2.5.1$, but must use the	applications, such as TSTool. Can use	
	installer option to create a JAR file in	Java code (but this code in a Python script	
	order to embed – this is the file that is	is only recognized by Jython). Integration	
	distributed with TSTool).	can occur within a running Java	
		application (essentially extending the	
		functionality of the Java application).	
Python	C, python	The original Python interpreter, which	
(www.python.org)	$(C: \forall Python 25)$	defines the Python language specification.	

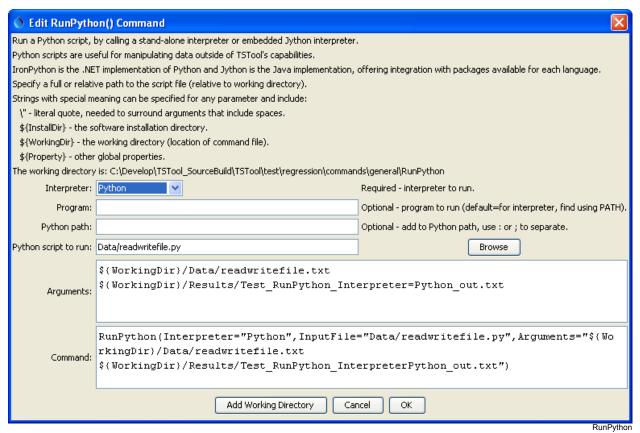

Python implementations have similar file organization, with the main executable (or batch file) residing in the main install folder. Core functionality is typically completely handled within the interpreter code and/or Python code included in the *Lib* folder under the main installation folder. Extended capabilities such as third-party add-ons are made available as module libraries that are installed in the *Lib\site-packages* folder. These folders are typically automatically included in the Python path and will be found when import statements are used in Python scripts. The folder for the main Python script that is run to start an execution is also typically included in the Python path by the interpreter at runtime. If any additional Python modules needed to be found, they can be added to the Python path at runtime (see the PythonPath command parameter below).

If the embedded Jython is used, then there may be no reliance on any other software if the core Python capabilities can be used. However, if third-party packages are used, it may be best to install them with the Jython distribution (e.g., in *Lib\site-packages*) so that the packages can be used for independent testing prior to use in the embedded interpreter. For example, perform a typical Jython install (e.g., into *C:\Jython2.5.1*), install the third-party packages into this location (using the installer for the package or directly copying into the *Lib\site-packages folder*), and then specify the PythonPath=C:\Jython2.5.1\Lib\site-packages) command parameter.

If a non-embedded approach is used, then IronPython, Jython, or Python must be installed on the computer for the appropriate Interpreter command parameter value. The interpreter program will be found if the installation folder is defined in the PATH environment variable, or use the Program command parameter to specify the full path to the interpreter program to run. The script is then run by running the following (see full parameter descriptions below):

Program InputFile Arguments

The following dialog is used to edit the command and illustrates the command syntax.

RunPython() Command Editor

The command syntax is as follows:

RunPython(Parameter=Value,...)

Command Parameters

Parameter	Description	Default
Interpreter	The Python interpreter to run, one of:	None – must be
	• IronPython	specified.
	• Jython	
	JythonEmbedded	
	Python	
	Global properties can be used with the \${Property}	
	syntax.	
Program	The Python interpreter program to run. Specify as a	Determined based on
	full path to the installed program, or only the program	the Interpreter
	name (in which case the path to the program must be	parameter:
	included in the PATH environment variable). Global	• IronPython: ipy
	properties can be used with the \${Property}	• Jython: jython
D +1 D +1	syntax.	Python: python
PythonPath	Additional locations for modules, to be added to the	None – the core Python
	Python path. Specify paths separated by; or: For	capabilities are available.
	embedded Jython, the sys. path is updated prior to	avanable.
	running the script. For non-embedded interpreters, the	
	JYTHONPATH environment variable is updated for the	
	interpreter, which results in sys.path being updated.	
	Global properties can be used with the \${Property} syntax.	
InputFile	The Python script to run, specified as an absolute path	None – must be
Impacrite	or relative to the command file. See the Arguments	specified.
	parameter for information about using properties to	specifica.
	specify the location. Global properties can be used	
	with the \${Property} syntax.	
Arguments	Arguments to pass to the script, such as the names of	None – arguments are
_	files to process. Use the \${WorkingDir} property	optional.
	to specify the location of the command file. Use	
	\${InstallDir} for the TSTool install folder. Use	
	\" to surround arguments that include spaces.	
	Separate arguments by a space. Global properties can	
	be used with the \${Property} syntax.	

The following command example illustrates how to run a Python script.

RunPython(InputFile="Data/readwritefile.py",
Interpreter="JythonEmbedded", Arguments="\${WorkingDir}/Data/readwritefile.txt
\${WorkingDir}/Results/Test RunPython Interpreter=JythonEmbedded out.txt")

The corresponding Python script is as follows:

```
# Test command for running Python script from TSTool
import sys
import os
print "start of script"
print 'os.getcwd()="' + os.getcwd() + '"'
infile = None
outfile = None
if (len(sys.argv) < 3):
    print "Error. Expecting input file name as first command line argument,
output file name as second."
   sys.exit(1)
else:
   infile = sys.argv[1]
    outfile = sys.argv[2]
   print 'Input file to process is "' + infile + '"'
   print 'Output file to create is "' + outfile + '"'
inf=open(infile,'r')
outf=open(outfile,'w')
for line in inf:
    outf.write("out: " + line)
inf.close()
outf.close()
print "end of script"
```

The data file is as follows:

```
Line 1 (first line)
Line 2
Line 3
Line 4
Line 5 (last line)
```

The output file is as follows:

```
out: Line 1 (first line)
out: Line 2
out: Line 3
out: Line 4
out: Line 5 (last line)
```

The following example illustrates the use of double quotes to surround Python script command-line arguments, to ensure that spaces and equal sign characters are properly handled:

```
# Retrieve the MEI (ENSO) index
WebGet(URI="http://www.esrl.noaa.gov/psd/data/correlation/mei.data",LocalFile="mei.data")
# Convert the MEI data file to a CSV file that can be read by TSTool
RunPython(Interpreter="Python",InputFile="mei2csv.py",Arguments="\"InputFile=${WorkingDir}/mei.data\"
\"OutputFile=${WorkingDir}/mei.csv\" \"LogFile=${WorkingDir}/mei2csv.log\"")
```
