Command Reference: ReadTableFromExcel()

Read a cell range from a Microsoft Excel file and create a new Table

Version 10.22.00, 2013-08-18

The ReadTableFromExcelFile() command reads a table from a Microsoft Excel file, more specifically from a worksheet in an Excel workbook file. A contiguous block of cells (rectangle) must be specified in one of the following ways:

- Specify a range of cells using Excel address notation (e.g., A1:D10)
- Specify the name of an Excel named range.
- Specify a table name (essentially a named range).

Table column types (number, text, etc.) are determined from the cells in the first data row being read (NOT the column name row) — data types must be consistent for all cells in a column, although blanks are allowed. Table column names are determined according to the ExcelColumnNames command parameter.

TSTool uses the Apache POI software, version 3.9 (http://poi.apache.org) to read the Excel file and consequently functionality is constrained by the features of that software package. The software reads and writes Excel files. It does not communicate with a running Excel program, as does other software tools (for example IronPython using Excel interoperability libraries). POI does not fully implement Excel functionality and consequently some formula capabilities are not available, which will generate errors getting values for some cells. One solution, for example to create test data in Excel, is to copy cells with "paste special" and then paste the values. It is expected that updates to POI will continue to add more formula support.

Table columns must contain consistent data types (all strings, all numeric, etc.). The following table describes how column types are determined and data values are transferred to the table. Column type determination uses the first data row in the specified address range. If a column is determined to be a type and then cell values in the column are different, conversions are made to maintain the intent of the values if possible. For example, a Boolean value stored in a cell will get converted to 1.0 if the table column has been determined to be for double precision numbers. Errors in processing cells may result in empty cell values in the output table.

Excel Data Type Conversion to Table

Excel Cell Format ("Number Category"	Conversion from Excel to TSTool Table
Number: General Number Currency Accounting Percentage Fraction Scientific Special Custom	 If Excel cell is internally a "numeric", convert to a double-precision number, where the format "Decimal places" is used in the TSTool table for formatting. The number of decimal places in Excel is fixed for some of the number categories shown on the left (e.g., Special=Zip Code). Excel internally stores integers as numbers with zero decimals. Need to figure out how to get the Excel cell formatting number of decimals to similarly set in the output table – but DO NOT assume zero decimals should convert to an integer. See the ExcelIntegerColumns parameter, which specifies the output table to use integers. If Excel cell is internally a "Boolean", convert to an integer having values 0 or 1. Need to evaluate having a parameter

Excel Cell Format ("Number Category"	Conversion from Excel to TSTool Table			
	ExcelBooleanColumns to transfer to a Boolean column in the output table. Excel seems to handle Booleans as text with values True or False.			
Date:	TSTool does not generally deal with only time and therefore implementation			
• Date	is limited. The POI library does not seem to have all date/time functions			
• Time	implemented.			
Text:	Converts to a string.			
• Text				
Blank	 Treated as Text (may in the future scan down the column to determine data type from first non-blank cell). Blank cells found once the column type is determined are set to empty strings in text columns, and null in number and date columns. 			
Error	 Treated as Text (may in the future scan down the column to determine data type from first non-error cell). Blank cells found once the column type is determined are set to empty strings in text columns, and null in number and date columns. 			
Formula	Expanded internally and the resulting cell value is set in the output table. POI does not support all formulas and errors may be generated, which resul in empty output table cells.			

Consider the following Excel worksheet example, which is equivalent to a comma-separated-value (CSV) file that has comments at the top and four columns:

	Α	В	С	D	Е	F
1	# INSIGHT dat					
2	# Mainly used to ensure constraint on time series					
3	Abbreviation	Base	Multiplier	IsIrregular		
4	Day	Day	1	0		
5	Month	Month	1	0		
6	Year	Year	1	0		
7						

ReadTableFromExcel SheetComments

Example Excel Workshet With Comments, Column Names, and Text and Integer Columns

Although it is possible to use comments in Excel (annotation on cells), these comments cannot be saved in simple text files like CSV files. Consequently, for transparency and automation of a full process, embedding comments in the worksheet may make sense. Note also that the numeric cells are formatted as type "Number" with 0 decimals in Excel. Internally, Excel does not have an integer data type and consequently it is difficult for the ReadTableFromExcel() command to know when to convert a zero-decimal number in Excel to a floating point or integer number in the output table (it therefore defaults to a floating point number in output). To make this conversion more explicit, use the ExcelIntegerColumns command parameter. The comment lines in the above example will be ignored in determining the headings, and any data rows that have a first cell value starting with the comment character will be ignored.

The following dialog is used to edit the command and illustrates the syntax for the command when reading the above Excel worksheet.

ReadTableFromExcel() Command Editor

ReadTableFromExcel

The command syntax is as follows:

ReadTableFromExcelFile(Parameter=Value,...)

Command Parameters

Parameter	Description	Default
TableID Identifier to assign to the table that is read, which		None – must be
	allows the table data to be used with other	specified.
	commands.	
InputFile	The name of the Excel workbook file (*.xls or	None – must be
	*.xlsx) to read, as an absolute path or relative to	specified.
	the command file location.	
Worksheet	The name of the worksheet in the workbook to	Read the first worksheet.
	read. Currently this is required if a specific sheet	If no address parameter is
	is read but in the future it may be made optional	specified, read the entire
	because the sheet can be determined from named	worksheet.
	range and table names (global resources in the	

Parameter	Description	Default
	workbook) and absolute Excel addresses that	
	include the sheet name.	
ExcelAddress	Indicates the block of cells to read into the table,	Must specify address
	using Excel address notation (e.g., A1:D10).	using one of available
		address parameters.
ExcelNamedRange	Indicates the block of cells to read into the table,	Must specify address
	using an Excel named range.	using one of available
		address parameters.
ExcelTableName	Indicates the block of cells to read into the table,	Must specify address
	using an Excel named range.	using one of available
		address parameters.
ExcelColumn	Indicate how to determine the column names for	ColumnN, <mark>or</mark>
Names	the table, one of:	FirstRowInRange
	• ColumnN - column name will be Column1,	when
	Column2, etc.	ExcelTableName is
	• FirstRowInRange - column names are	specified?
	taken from the first non-comment row in the	
	address range	
	RowBeforeRange - column names are	
	taken from the first non-comment row before	
	the address range	
ColumnExclude	Indicate column names (as assigned by	Include all rows.
Filters	ExcelColumnNames) and pattern to use to	
	exclude rows. For example, exclude rows with	
	blanks in columns. The format of the parameter	
	is:	
	ColumnName1:Pattern1,	
	ColumnName2:Pattern2,	
	where patterns can contain * to match a substring.	
Comment	Specify the character that if found at the start of	No comments are used.
	the first column in a row (not just the specified	
	address range) indicates that the row is a comment	
	and can be ignored in transferring data to the	
	output table. Comments are particularly useful	
	when processing entire data sheets.	
ExcelInteger	Indicate the names of columns (separated by	Numeric columns are
Columns	commas) that should be treated as integer	treated as double-
	columns in the output table.	precision values in the
		output table.
NumberPrecision	The number of digits to the right of the decimal to	6
	use for numeric columns that are not identified as	
	integer columns. Currently the cell formatting	
	information is not interpreted to determine	
	precision.	
ReadAllAsText	Indicate with True or False whether all	False — set table
